Abstract

A series of linear acrylic copolymers based on Isobornyl acrylate (IBOA) and isobutyl acrylate (IsoBA) were elaborated by radical photopolymerization. In addition, several photochemically crosslinked poly(IBOA-co-IsoBA) were prepared by introducing small amounts of 1,6-hexanedioldiacrylate as crosslinking agent. The evolution of the glass transition temperature was determined experimentally by Differential Scanning Calorimetry as a function of composition for both linear and crosslinked poly(IBOA-co-IsoBA), yielding T_g values ranging from (~249K) to (~315K). Theoretical modeling was performed applying Fox, Gordon-Taylor and Couchman-Karasz models by simple calculations using experimental data, leading to only fair agreement between theoretical and experimental values, or by applying fitting procedures involving one or two adjustable parameters. Likewise, the Kwei model, known to take into account hydrogen bonding interactions between monomers, could not describe well the evolution of T_g, indicating the existence of other factors influencing T_g. Finally, a thermodynamic approach based on entropy considerations allowed to attribute an explanation of the evolution of T_g.

INTRODUCTION

Improvement of thermal and mechanical properties of a polymeric material can be achieved by associating two or more polymers (copolymer, terpolymer, etc.).[1-4] However, combining several amorphous polymers possessing different structural units can influence the glass transition temperature (T_g).[5-7] The latter is considered as a specific major transition for each polymeric material which determines its field of practical applications such as adhesives or coatings. The T_g represents a critical temperature beyond which the translational movement of the polymer chain is active. At this temperature, a transition from the glassy state to the rubbery state takes place, defining thus the range of operating temperatures of the material.[8] Below T_g the polymer chains in their amorphous state are frozen; only vibrational movements are active in this state. From a practical point of view, different common techniques allow to determine T_g experimentally, such as: DSC (Differential Scanning Calorimetry),[9] DMA (Dynamic Mechanical Analysis),[10] FTIR (Fourier Transform Infrared Spectroscopy).[11].

Recently much interest was given to acrylic copolymers based on isobornylacrylate (IBOA), since various applications are possible in different domains.[12,13a,14-16] Poly(IBOA) has a large cyclic side group providing stiffness, low absorption and a relatively high T_g well above ambient temperature, which is situated close to that of poly(methylmethacrylate) (PMMA) and poly(styrene).[17] A literature survey unveils that only a few studies have been carried out to examine thermal properties of IBOA copolymers. In a recent report, Ko *et al.* described an increase of the thermal resistance by introducing isobornylmethacrylate (IBOMA) into poly (MMA-co-cyclohexylmaleimide), thus creating a ter-copolymer.[12] Jakubowski *et al.* investigated the thermal behavior of poly (IBOA-co-n-butylacrylate) by varying the ratio of IBOA and n-butylacrylate monomers.[18] DSC studies have revealed that these copolymer systems exhibit unique glass transition temperatures indicating the absence of phase separation effects. In this work thermal properties of photochemically elaborated linear and

3

65 crosslinked poly (IBOA-co-Isobutylacrylate) were examined experimentally by DSC

66 measurements as function of initial monomer composition. Isobutylacrylate (IsoBA) was

67 selected as co-monomer together with IBOA due to the large difference between the T_g's of

68 the two corresponding homopolymers. The T_g of poly (IBOA-co-IsoBA) could thus be varied

69 over a wide range of temperatures, which might be useful for specific temperature dependent

70 applications such as coatings with antibacterial and antimicrobial adhesion properties.[15,16]

71 Indeed, these reports show that the resistance of polyurethanes at low temperature could be

72 considerably improved by modulating the T_g of the polymer. This was achieved by

73 incorporation of IBOA in the polymer, yielding a high-performance antibacterial material.[16]

74 An attempt was made to describe the obtained experimental T_g data of linear and crosslinked

75 poly (IBOA-co-IsoBA) applying theoretical models, by performing adjustment procedures

76 (fitting) using data analysis software Origin and R.

77

Theoretical approaches to describe the evolution of T_g

79 Different approaches, such as those based on kinetical and/or thermodynamical considerations

80 have been proposed to describe the dependence of T_g on the sample composition, mainly of

81 polymer blends.[19-29] These models rely generally on the additivity of the properties of the

82 components of the mixture. For example, Weng *et al.*[19] studied the effect of salt on T_g of

83 sugars using Fox[20] and Gordon and Taylor (G-T)[21] models to describe their thermal behavior.

84 Kuo *et al.*[22] applied the G-T approach to predict T_g of Poly (MAAM-co-MMA). The Fox

85 equation is expressed as

86 $$\underline{\quad} \quad \underline{\quad} \quad \underline{\quad}$$ (1)

87 where T_g and $T_{g,i}$ represent the glass transition temperatures of the mixture and of their pure

88 components i (i=1,2), and x_i is the mass fraction of component i. The G-T equation, which is

89 based on the additivity rule of specific volumes of a two-component system (1 and 2), has

4

90 proved its reliability in predicting T_g values of blends of linear polymers and mixtures of

91 polymers with plasticizers :

92 $$\rule{3cm}{0.4pt}\qquad\qquad (2)$$

93 where $K_{G\text{-}T}$ represents the G-T constant, which was evaluated applying the Simha-Boyer

94 rule[27,28]

95 $$\rule{1.5cm}{0.4pt}\qquad\qquad (3)$$

96 where ρ_1 and ρ_2 stand for the volume densities of components 1 and 2, respectively.

97 The Couchman-Karasz (C-K) equation[23,24] has been developed on the basis of the classical

98 thermodynamic theory, considering that the binary system behaves purely conformational.

99 This approach, assuming that the glass transition represents a thermodynamic event, weights

100 the T_g of the single components by the change in heat capacity (ΔC_p) instead of the volume

101 change occurring at the T_g of the binary system. ΔC_{p1} and ΔC_{p2}, corresponding to the isobaric

102 heat capacity increments of pure components 1 and 2, are supposed to be temperature

103 independent. The C-K equation can be written as follows :

104 $$\rule{3cm}{0.4pt}\qquad\qquad (4)$$

105 Kwei[25] demonstrated that the evolution of T_g of mixtures of linear polymers might deviate

106 from the G-T equation, due to specific interactions related to the presence of hydrogen bonds

107 between the components. Kwei modified the G-T equation by introducing a second

108 parameter, q, to take into account these interactions :

109 $$\rule{3cm}{0.4pt}\qquad\qquad (5)$$

110 The K_{KW} constant is defined in the same way as $K_{G\text{-}T}$.

111

112   **EXPERIMENTAL**

113   **Materials**

114   IsoBA, IBOA, and the crosslinking agent 1,6-hexanedioldiacrylate (HDDA) were purchased

115   from Sigma-Aldrich (Saint-Quentin Fallavier, France). The photoinitiator used was 2-

116   hydroxy-2-methyl-1-phenyl-propane-1 (commercial designation: Darocur 1173), also

117   obtained from Sigma-Aldrich.

118

119   **Sample preparation**

120   Linear poly(IBOA-co-IsoBA) copolymers were prepared as function of composition of the

121   mono-functional monomers IsoBA and IBOA. Copolymer networks with different cross-

122   linking densities were elaborated as well, using the same monomers together with HDDA

123   concentrations comprised between 0.1 and 0.7 weight-% (wt-%). The amount of

124   photoinitiator was kept constant for all samples at 0.5 wt-% of the total monomeric blend.

125   Mixtures of the monomers were stirred for 3 hours to homogenize the solutions, and then

126   these blends were put in Teflon molds and exposed to UV-visible radiation with a wavelength

127   of 365 nm and an intensity of 1.5 mW / cm^2. These free radical copolymerization/crosslinking

128   reactions were carried out under nitrogen to prevent inhibition effects, and the exposure time

129   was set to 35 min to achieve complete conversion of all reactive acrylic monomers in the

130   precursor systems. The copolymer samples obtained were optically transparent with variable

131   rigidity at room temperature, i.e. an increase of stiffness was observed for samples with

132   increasing amount of IBOA.

133   Figure 1 represents schematically the sample preparation route for the two copolymer

134   architectures which have been investigated, i.e. linear and photochemically crosslinked

135   poly(IBOA-co-IsoBA).

6

136
137

Figure 1. Elaboration of linear and photochemically crosslinked poly(IBOA-co-IsoBA).

139

Determination of molar weight by size exclusion chromatography

Size exclusion chromatography (SEC) measurements were performed at room temperature on

a Waters Alliance e2695 system using THF as solvent (flow rate = 1 mL / min) and equipped

with three columns placed in series (Styragel HR1, Styragel HR3, Styragel HR4). A Wyatt RI

(differential refractive index) detector and a Wyatt MALS (Multi Angle Light Scattering)

detector (laser $\lambda = 670$ nm) were coupled to the system. Calibration was established with

polystyrene (PS) standards from Polymer Laboratories.

147

Thermal properties investigated by differential scanning calorimetry

Thermal properties of the obtained homo- and copolymers were studied by DSC (Perkin-

Elmer model 8000). The instrument was calibrated with indium and zinc as standards,

applying a heating rate of 10°C / min. All experiments were conducted under nitrogen flow

152   (20 mL / min). Samples were prepared by introducing about 8-10 mg from arbitrary positions

153   of the disk-shaped polymer samples into aluminum DSC crucibles.

154   T_g was observed as a baseline shift related to a heat capacity change (ΔC_p) of the sample. It is

155   well-known that measurement of T_g depends to a great extent on experimental parameters,

156   such as heating and cooling rates. In order to obtain coherent T_g results for various amorphous

157   copolymers in this work, a rate of 10°C / min (heating and cooling cycles) was applied in the

158   temperature range from -72°C to 120°C. The program consisted first in cooling the sample,

159   followed by three heating and cooling cycles to take into account eventual thermal events

160   related to the sample preparation history. A Pyris computer software from Perkin-Elmer was

161   used to determine T_g from the midpoint of the transition range of the thermograms. Only

162   thermograms from the second heating scan were considered for the analysis.

163

164   *Analysis by FTIR spectroscopy*

165   Fourier Transform Infrared spectra (FTIR) of the elaborated linear polymer films were

166   recorded in Attenuated Total Reflection (ATR) mode at room temperature on a Perkin Elmer

167   Frontier spectrometer in the wavenumber range between 4000 cm^{-1} and 600 cm^{-1} with a

168   spectral resolution of 4 cm^{-1} applying 32 scans.

169

170   **RESULTS AND DISCUSSION**

171   **Characterization of Poly(IBOA-co-IsoBA)**

172   The technique of free radical photopolymerization was applied to elaborate linear and

173   crosslinked Poly(IBOA-co-IsoBA) samples. The crosslinking degree was changed for the

174   latter by adding different small amounts of HDDA as crosslinking agent into the initial

175   monomeric blends. The structure of all elaborated copolymers was evidenced by immersion

176   of the polymerized samples in a good organic solvent, Tetrahydrofuran (THF). Chemically

177   crosslinked polymer networks have indeed been formed for compositions containing HDDA,

178   i.e. the disk-shaped samples immersed in THF present strong swelling effects, but did not

179   dissolve in the presence of the solvent. On the other hand, the elaborated linear copolymers

180   were found to be perfectly miscible in THF thus confirming their linear structure.

181
182   **Figure 2.** Dependence of copolymer composition on SEC measurements for linear Poly

183   (IBOA-co-IsoBA) samples.

184

185   Figure 2 presents elugrams from SEC measurements for linear Poly (IBOA-co-IsoBA), as a

186   function of copolymer composition. Some broadening of the molecular weight distribution

187   could be observed with increasing IBOA content, but the average molecular weight of all

188   copolymers remain roughly constant, indicating that the experimental results obtained from

189   analysis of thermal properties do not depend on eventual differences in molecular weight.

9

190

191

192
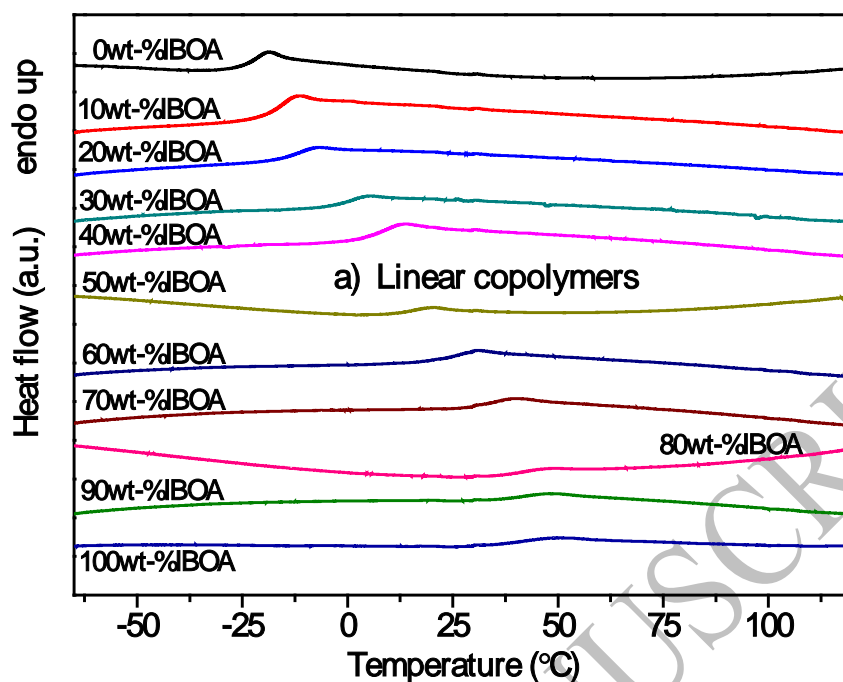

Figure 3. Thermograms obtained by DSC as functions of temperature and weight percentage

of IBOA for (a) linear Poly(IBOA-co-IsoBA) and (b) Poly (IBOA-co-IsoBA), crosslinked

195 with 0.5 wt-% HDDA.[13b]

196

197 Figure 3 shows the thermograms of linear [Figure 3(a)] and photochemically crosslinked

198 [Figure 3(b)] Poly(IBOA-co-IsoBA) samples as function of the initial monomer composition,

199 acquired by DSC measurements. Interestingly, only one single glass transition was observed

200 as thermal event for all samples, on the temperature range explored between -72°C and

201 120°C. Since only one glass transition was observed for all copolymer samples, it can be

202 deduced that the analyzed systems could be considered as miscible from a thermodynamical

203 point of view.[24] Semi-miscible and immiscible copolymers generally show two T_g values

204 independent of the sample composition, corresponding to the T_g's of their respective pure

205 components. Figure 3 reveals that the T_g values increase significantly with the increase of the

206 wt-% of IBOA in the copolymer. In particular, T_g changes from -24°C to 41°C, when

207 increasing the amount of IBOA from 0 wt-% to 100 wt-% in the case of linear copolymers

208 [Figure 3(a)]. In the same way the T_g values increase from -24°C to 43.9°C when increasing

209 the amount of IBOA from 0 wt-% to 100 wt-% for copolymers crosslinked with 0.5 wt-% of

210 HDDA [Figure 3(b)].

211 Figure 4 presents experimentally obtained T_g data for all linear and crosslinked Poly(IBOA-

212 co-IsoBA), following an "S"-shaped form as function of sample composition. Interestingly,

213 the T_g values obtained for linear copolymers appear to be close to those of the networks

214 prepared using 0.1 wt-% up to 0.7 wt-% HDDA.
Figure 4. Evolution of the single glass transition temperature as function of the weight ratio of the IBOA monomer for linear and crosslinked Poly (IBOA-co-IsoBA). Experimental error bars are all smaller than the size of the data point symbols. The continuous line represents a guide to the eye.

The data presented in Table 1 allow a more detailed analysis of the dependence of T_g on composition and structure of the copolymers. Within the limits of experimental errors, a slight tendency of increasing T_g values can be observed especially for higher IBOA concentrations when comparing the case of linear Poly (IBOA-co-IsoBA) with the crosslinked copolymers in the following order 0.1 wt-% / 0.3 wt-% / 0.5 wt-% / 0.7 wt-% HDDA in the precursor blends.

Composition IBOA (wt-%)	Linear T_g (K)	0.1 wt-% HDDA T_g (K)	0.3 wt-% HDDA T_g (K)	0.5 wt-% HDDA T_g (K)	0.7 wt-% HDDA T_g (K)
0	248.9	248.5	248.2	249.1	249.1
10	252.9	253.5	253.5	255.0	253.5

227

228   **Table 1.** Comparison between experimentally measured glass transition temperatures of linear

229   and crosslinked Poly (IBOA-co-IsoBA).

230

231   Nevertheless, since these thermal events were found to be rather similar for both copolymer

232   structures, theoretical models were applied on linear and on crosslinked Poly (IBOA-co-

233   IsoBA) as well, to describe the evolution of T_g as function of sample composition. The

234   applied theoretical approaches, which have been originally established for linear binary

235   systems, take into account the equations developed by Fox, G-T, C-K, and Kwei. For the sake

236   of simplicity, only the outcome from linear Poly(IBOA-co-IsoBA) and the crosslinked system

237   with 0.1 wt-% HDDA were presented here.

Fox model

G-T model

	K (G-T)

0.1 wt-%HDDA	0.353	0.151

239 **Figure 5.** Evolution of T_g as a function of weight ratio of IBOA: Comparison of the

240 experimental results with data calculated using the following equations (a) Fox, (b) Gordon

241 and Taylor (G-T), and (c) Couchman and Karasz (C-K), for linear and crosslinked Poly

242 (IBOA-co-IsoBA) with 0.1 wt-% of HDDA.

243

244 **Theoretical description of the glass transition temperature**

245 *Models without adjustment procedure*

246 The evolution of T_g of binary copolymers as function of sample composition has been

247 described in literature by Fox,[20] G-T,[21] and C-K.[23] Figure 5 presents experimental data and

248 values calculated according to these approaches without applying an adjustment procedure,

249 for linear and crosslinked Poly (IBOA-co-IsoBA) with 0.1 wt-% of HDDA. Figure 5(a) shows

250 that the Fox equation fail to describe the evolution of T_g as a function of sample composition,

251 probably due to strong asymmetric contributions of polymeric IBOA and IsoBA. A

252 comparison of experimental data with results calculated from the G-T approach is presented

253 in Figure 5(b), yielding only a fair description of the experiments. Figure 5(c) shows a rather

254 strong discrepancy between theory and experiments, by application of the C-K model.

255

256 *Models applying an adjustment procedure*

257 Origin and R softwares were applied to carry out adjustment (fitting) procedures (least

258 squares method) of parameter values included in the models of G-T [Eq. (2)], C-K [Eq. (4)],

259 and Kwei [Eq. (5)]. Obviously application of adjustment procedures leads to a better but not

260 perfect description of the experimental data as can be seen on Figure 6(a), where the K_{GT}

261 parameter from the G-T model was determined as 0.73 and 0.68 for linear and cross-linked

262 Poly (IBOA-co-IsoBA) with 0.1 wt-% HDDA, respectively. Similar remarks can be made for

263 the C-K model shown in Figure 6(b). A better adjustment of the theoretical description to the

264 experimental data was observed compared to the model without adjustment parameter. K_{C-K}

265 was found equal to 0.73 and 0.67 for the linear copolymer and the crosslinked Poly (IBOA-

266 co-IsoBA) with 0.1 wt-% HDDA, respectively. These values suggest that IBOA is slightly

267 dominant in its contribution to the T_g of the copolymer. While the G-T model describe well

268 the experimental data between 0.4 wt-% and 0.7 wt-% IBOA, the adjustment becomes less

269 efficient when approaching the extremities of the phase diagrams.

270 Application of the Kwei Eq. (5), containing an additional parameter (q) to be adjusted, did not

271 yield a better description of the experimental data than that obtained from the G-T and C-K

272 equations [(Figure 6(c)]. The values of K_{KW} for both linear and crosslinked Poly (IBOA-co-

273 IsoBA) with 0.1 wt-% of HDDA were found to be identical and close to 1, probably related to

274 a limitation effect of the adjustment procedure. On the other hand the Kwei equation has

275 already been successfully applied to describe a complex S-shaped evolution of T_g as function

276 of composition as shown by Weng *et al.* for sugar-salt mixtures.[19] The situation here is

277 different probably due to the fact that the S-shaped evolution is less pronounced in Figure 6(b)

278 than in Ref. 19, requiring a fitting procedure involving more than 2 parameters to be adjusted.

279
281 **Figure 6.** Results from modeling the evolution of T_g as a function of the weight ratio of IBOA

282 by the equations of (a) Gordon and Taylor (G-T), (b) Couchman and Karasz (C-K), and (c)

283 Kwei for linear and crosslinked Poly (IBOA-co-IsoBA) with 0.1 wt-% of HDDA.

284

285 It can be concluded that the models applied above were not satisfactory to predict the

286 compositional evolution of experimentally obtained T_g values of poly(IBOA-co-IsoBA). A

287 possible source of discrepancies between theory and experiment could be the change of the

288 entropy mixing term occurring at the transition from glassy to rubbery states, which was not

289 considered by the previously used models. The presence of polymer chain units exhibiting

290 different structural chain mobility like the rigid IBOA and the flexible IsoBA monomeric

291 units in the copolymer might lead to deviations of the compositional dependencies of the

292 entropic contributions. In order to take into account the contribution of the entropy change

293 (ΔS_{mix}) at T_g, the approach from Pinal et al.[30] was applied, which provides a direct

294 relationship between ΔS_{mix} and T_g :

$$ \quad (6) $$

295 where $T_{g,C-K}$ represents T_g of the copolymers obtained from the C-K model [Eq. (4)] and

296 $\Delta C_{p,mix}$ stands for the composition dependent heat capacity change of the copolymers at the

297 experimentally determined T_g's. In order to calculate ΔS_{mix}, Eq. (6) can be rewritten as

298 follows:

$$ \quad (7) $$

299

300

18

301
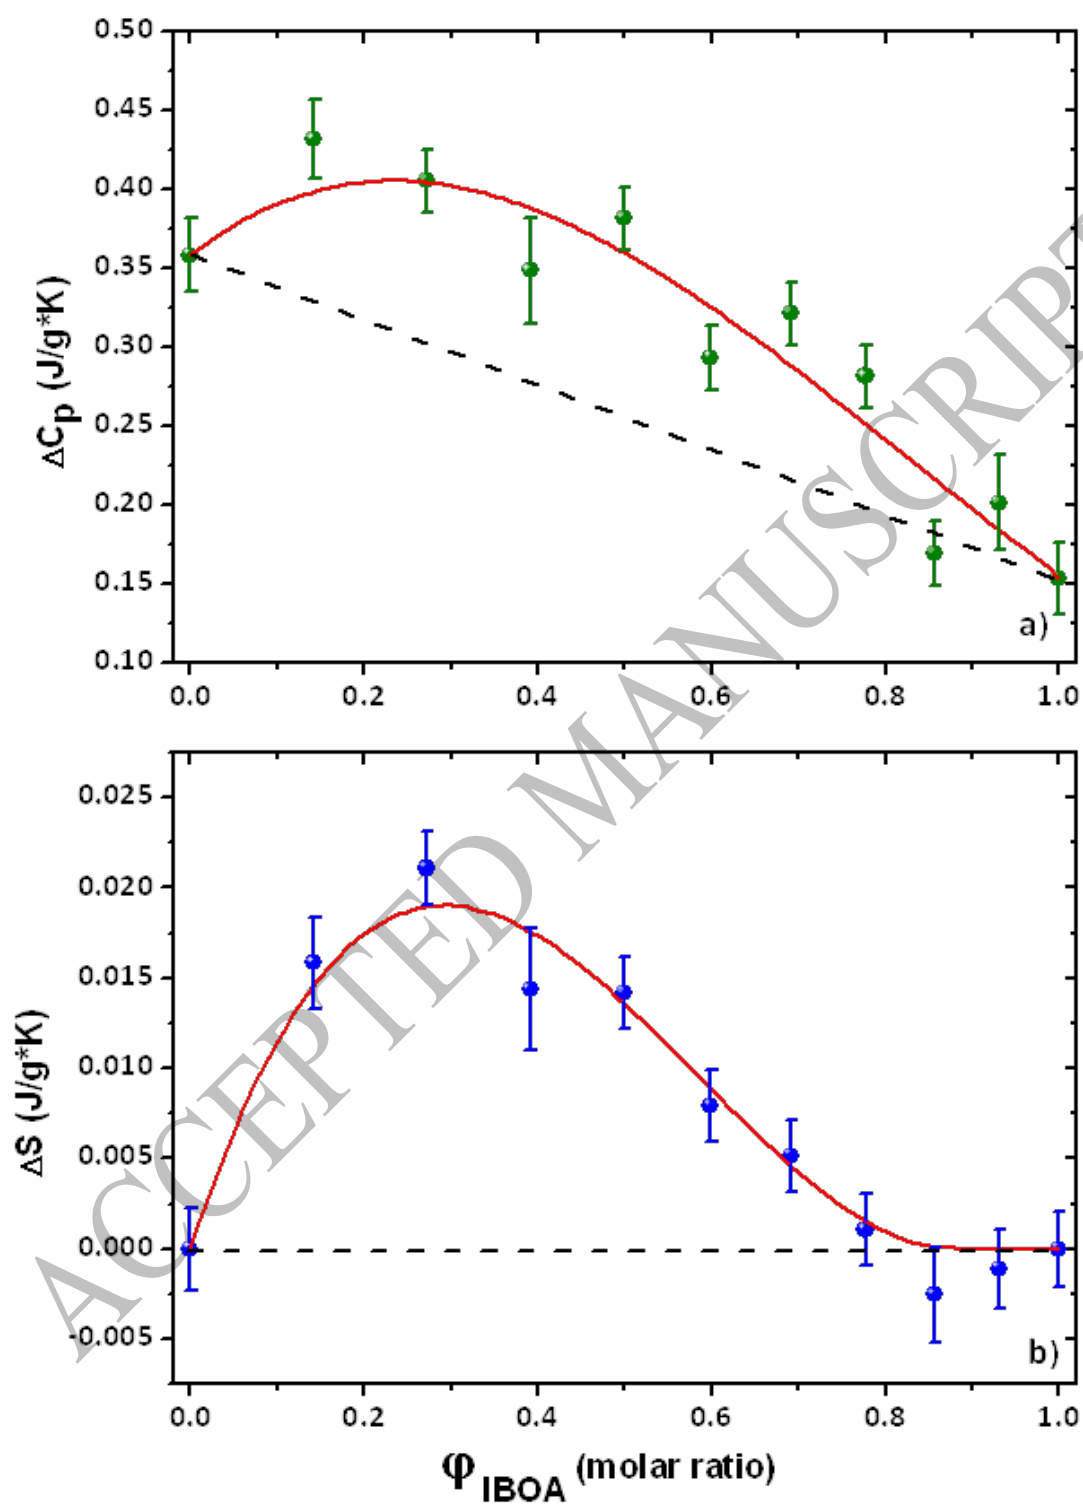

Figure 7. Composition dependence of a) $\Delta C_{p,mix}$ and b) ΔS_{mix} for linear poly(IBOA-co-IsoBA). The dashed straight lines between the data of the pure homopolymers poly(IBOA) and poly(IsoBA) correspond to the case $\Delta S_{mix} = 0$. The smooth lines represent guides for the eyes, and follow the data points.

The composition dependence of $\Delta C_{p,mix}$ is plotted in Figure 7(a) for the case of linear poly (IBOA-co-IsoBA). The copolymer data exhibit a positive deviation from linearity which is given by a straight line between the two ΔC_p values of the homopolymers, indicating the presence of specific interactions between IBOA- and IsoBA-units. Using the outcome of Figure 7(a), ΔS_{mix} could be calculated following Eq. (7). Figure 7(b) represents ΔS_{mix} as function of copolymer composition, exhibiting small positive entropy changes for copolymer compositions up to an IBOA molar fraction of 0.75. ΔS_{mix} data above this molar fraction show values around 0 within the error bars. These results can be explained by the presence of specific inter- and intramolecular interactions, which increase with more enhanced chain mobility related to the increase of the amount of the flexible IsoBA in the copolymer. At $\varphi_{IBOA} = 0.85$, ΔS_{mix} presents a negative value due to a down-shifted data point of ΔC_p in Figure 7(a), at the same molar fraction. ΔS_{mix} could thus be considered either positive or zero for all copolymer compositions.

An attempt was made to seek for experimental evidence of the existence of IBOA and IsoBA interactions. In particular, the low frequency region of infrared spectra reveals, among others, vibrational modes of inter- and intramolecular hydrogen bonding. It is well-known that such interactions lead to significant changes of vibrational modes in the IR spectrum, like frequency shifts in the order of magnitude of hundreds of cm^{-1} and increases of IR intensity for bands related to vibrational modes of functional groups directly involved in the hydrogen-bonded bridges.

20

327 Infrared spectroscopic analysis by the ATR method was conducted at ambient temperature on

328 linear Poly (IBOA-co-IsoBA) samples by varying the IBOA/IsoBA ratio in the precursor

329 blends (Figure 8). For copolymers containing 50-90 wt-% IBOA, a broad absorbance band

330 appeared in the low frequency region from 3100 cm^{-1} to 3700 cm^{-1}, characteristic for the O-H

331 stretching region. Interestingly this band was absent in the case of the homopolymer Poly

332 (IsoBA) and only a broad band of low intensity exhibiting a maximum around 3300 cm^{-1} was

333 observed for Poly (IBOA). Moreover, a shift of this maximum of approximately 100 cm^{-1} to

334 higher wavenumbers was observed by increasing the content of IsoBA within the copolymer

335
336 **Figure 8.** Experimental evidence of the existence of hydrogen bonding interactions by ATR-

337 FTIR spectroscopy analysis of linear Poly (IBOA-co-IsoBA).

338

339 from 0 to 80 wt-%. The intensity of this band increases from 0 to 30 wt-% IsoBA then

340 decreases from 30 to 80 wt-% IsoBA. It can be assumed that hydrogen bonding interactions

341 could occur between a positively charged hydrogen atom and an electronegative atom like

342 oxygen from carbonyl groups. In the case of IBOA, Figure (6) of Ref. 31, presenting the [1]H-

343 NMR spectrum of linear Poly(IBOA), shows that the Methine proton H_9 appears deshielded at

344 4,6 ppm due to the vicinity of the carboxyl group, and might therefore be a good candidate for

345 hydrogen bonding.

346 As a result, mobility of the main chain might be hindered by the existence of non-covalent

347 O•••H•••O•••H sequences among the side chains. This might also explain the relatively low T_g

348 value obtained for Poly(IBOA) (Figure 3) instead of $T_g = 94°C$,[17] in spite of the high

349 molecular weight of Poly(IBOA). However, the O•••H sequences dissociate easily by

350 increasing temperature. An evidence of gradual dissociation of the O•••H•••O•••H type of

351 hydrogen-bonds with increasing temperature could we observed in the O-H stretching region

352 (Figure 8), in relationship with the T_g dependence of the copolymer composition. Indeed, T_g

353 of copolymers including 50 wt-% and more of IBOA were found below ambient temperature

354 and present hydrogen bonding interactions. On the other hand, copolymers with IBOA

355 content lower than 50 wt-% present glass transitions above room temperature together with

356 the absence of hydrogen bonding.

357

358 **CONCLUSIONS**

359 Linear and photochemically crosslinked poly(IBOA-co-isoBA) were successfully elaborated

360 and characterized by GPC, FTIR and DSC techniques. A single glass transition was observed

361 for all samples, and the graphical presentation of T_g as function of sample composition

362 revealed a characteristic S-shaped form.

363 The equations of Fox-, G-T- and C-K-models, based on the assumption of free volume

364 additivity, fail to describe the concentration dependant evolution of T_g of poly(IBOA-co-

365 IsoBA), even if the K_{G-T} and K_{C-K} parameters were optimized using fitting procedures.

366 Slightly better adjustment results were obtained using the Kwei approach providing a second

367 adjustment parameter q. The discrepancies between theory and experiment could be removed

368 by taking into account the entropy change of mixing presenting small positive values,

369 indicating the presence of inter- and intramolecular interactions. In particular FTIR

370 spectroscopic measurements carried out at ambient temperature confirmed the presence of

371 strong hydrogen bonding particularly for intermediate IBOA/IsoBA compositions.

372

373 **DECLARATION OF COMPETING INTEREST**

374 The authors declare that they have no known competing financial interests or personal

375 relationships that could have appeared to influence the work reported in this paper.
