#### Abstract

**Background:** Effective inhibition of plasma kallikrein may have significant benefits for patients with hereditary angioedema due to deficiency of C1 inhibitor (C1-INH-HAE) by reducing the frequency of angioedema attacks. Avoralstat is a small molecule inhibitor of plasma kallikrein. This study (OPuS-2) evaluated the efficacy and safety of prophylactic avoralstat 300 or 500 mg compared with placebo.

**Methods:** OPuS-2 was a Phase 3, multicenter, randomized, double-blind, placebo-controlled, parallel-group study. Subjects were administered avoralstat 300 mg, avoralstat 500 mg, or placebo orally 3 times per day for 12 weeks. The primary efficacy endpoint was the angioedema attack rate based on adjudicator-confirmed attacks.

**Results:** A total of 110 subjects were randomized and dosed. The least squares (LS) mean attack rates per week were 0.589, 0.675, and 0.593 for subjects receiving avoralstat 500 mg, avoralstat 300 mg, and placebo, respectively. Overall, 1 subject in each of the avoralstat groups and no subjects in the placebo group were attack-free during the 84-day treatment period. The LS mean duration of all confirmed attacks was 25.4, 29.4, and 31.4 hours for the avoralstat 500 mg, avoralstat 300 mg, and placebo groups, respectively. Using the Angioedema Quality of Life Questionnaire (AE-QoL), improved QoL was observed for the avoralstat 500 mg group compared with placebo. Avoralstat was generally safe and well tolerated.

**Conclusions:** Although this study did not demonstrate efficacy of avoralstat in preventing angioedema attacks in C1-INH-HAE, it provided evidence of shortened angioedema episodes and improved QoL in the avoralstat 500 mg treatment group compared with placebo.

#### KEYWORDS

C1 inhibitor, hereditary angioedema, oral kallikrein inhibitor, prophylaxis

## 1 | BACKGROUND

Hereditary angioedema (HAE) with C1 inhibitor deficiency (C1-INH-HAE) is an autosomal dominant disorder characterized by recurrent episodes of swelling of the skin, pharynx, larynx, gastrointestinal tract, genitals, and extremities,<sup>1</sup> and is due primarily to mutations in the *SERP-ING1* gene that results in insufficient production of the natural plasma kallikrein inhibitor, C1 inhibitor (C1-INH). C1-INH is a serine protease inhibitor (serpin) that prevents uncontrolled contact activation and bradykinin (BK) production by covalently binding to and inactivating kallikrein, a serine protease integral to the contact activation pathway.<sup>2</sup> Extensive evidence from animal models and clinical studies supports the

role of BK as the principal mediator of the signs and symptoms of C1-INH-HAE.<sup>3-5</sup> Activation of the BK B2 receptor by BK results in vasodilatation, increased vascular permeability, and smooth muscle contraction, all of which contribute to the angioedema attacks in C1-INH-HAE patients.<sup>3</sup> Oropharyngeal and laryngeal swelling can be life-threatening. Angioedema attacks in other sites, including the limbs, genitalia, face, and intestines, can be painful, disabling, and disfiguring, and have a significant impact on functionality and quality of life of the patients.<sup>6-9</sup>

The effective management of C1-INH-HAE involves the prevention and treatment of angioedema attacks.<sup>10</sup> Kallikrein is a proven target in the treatment of C1-INH-HAE. In the EU and the United States, licensed therapy for long-term or routine prevention of angioedema

attacks is limited to purified plasma-derived C1-INH administered intravenously (Cinryze®) or subcutaneously (Haegarda® – USA only) every 3–4 days; oral doses of attenuated androgens (such as danazol) are also prescribed for C1-INH-HAE attack prophylaxis. While administration of androgens is convenient, unacceptable adverse effects (such as androgenic hormonal effects, intracranial hypertension, and hepatocellular adenoma and carcinoma) and contraindications (including pregnancy and pediatrics) limit their clinical use.<sup>10,11</sup>

Avoralstat (formerly BCX4161) is a potent, small molecule inhibitor of kallikrein that was discovered at BioCryst Pharmaceuticals, Inc.<sup>12</sup> Effective inhibition of kallikrein with an orally bioavailable small molecule such as avoralstat may have significant benefits for patients with C1-INH-HAE by reducing the frequency of angioedema attacks. In a prior Phase 2 study, the safety and efficacy of avoralstat 400 mg taken 3 times per day were evaluated as a prophylactic treatment to reduce the frequency of angioedema attacks in subjects with C1-INH-HAE.<sup>13</sup> Treatment with avoralstat resulted in significantly fewer angioedema attacks per week, demonstrating proof of concept for avoralstat in the prevention of angioedema attacks in subjects with C1-INH-HAE. In the Phase 2 study, treatment with avoralstat also showed statistically significant improvements in subject quality of life (QoL), severity of disease, and number of attack-free days. Avoralstat was generally well tolerated with no discontinuations due to drug-related adverse events (AEs), no Grade 4 AEs or treatment-related serious adverse events (SAEs), and few Grade 3 AEs or laboratory abnormalities.

This OPuS-2 Phase 3 study evaluated the efficacy and safety of prophylactic avoralstat 300 and 500 mg administered 3 times per day for 12 weeks compared with placebo, assessed the effects of avoralstat on C1-INH-HAE disease activity and angioedema attack characteristics. This study also evaluated the effects of avoralstat on patients' QoL and described the population pharmacokinetics (PK) of avoralstat.

## 2 | METHODS

### 2.1 | Study design

OPuS-2 was a Phase 3, multicenter, randomized, double-blind, placebo-controlled, parallel-group study performed at 46 centers in North America and Europe. Eligible subjects, stratified by screening angioedema attack rates ( $\geq 1$  attack per week vs  $< 1$  attack per week), were randomized in a 1:1:1 ratio to receive avoralstat 500 mg, avoralstat 300 mg, or placebo administered orally 3 times per day for 12 weeks. Details of HAE attacks were recorded in an electronic diary. Attacks were treated in accordance with the subject's normal standard of care.

The OPuS-2 trial (www.clinicaltrials.gov ID# NCT02303626 and EudraCT # 2014-002655-26) was approved by independent ethics committees or institutional review boards. All patients provided written informed consent.

### 2.2 | Subjects

Subjects aged  $\geq 18$  years of age with a clinical diagnosis of type 1 or 2 C1-INH-HAE as documented by either a low C1 INH antigenic

level (Type I HAE) or a normal C1-INH antigenic level and a low C1 INH functional level (Type II HAE) were eligible. Documentation of minimum angioedema attack rate of 2 per month was required, either by audit of medical record (at least 2 angioedema attacks per month for 3 consecutive months within the 6 months prior to screening) or a subject diary record of at least 4 unique angioedema attacks collected in a run-in period of a maximum of 2 months, with at least 1 attack occurring each month. Use of C1INH or tranexamic acid within 7 days prior to the screening visit or expected use at any time during the study was exclusionary. The use of androgens within 30 days was also an exclusion criterion unless the subject was receiving a stable dose of androgens at least 90 days prior to the screening visit, met the required angioedema attack frequency while on the stable dose, and planned to remain on the current dose of androgens during the study.

### 2.3 | Study treatment

Subjects received avoralstat 500 mg, avoralstat 300 mg, or placebo administered orally 3 times per day for 12 weeks, and were asked to avoid taking study drug with food. Study drug assignment was blinded to the investigator and clinical site personnel, study subjects, and study staff.

### 2.4 | Study measures

The primary efficacy outcome was weekly angioedema attack rate based on the number of confirmed episodes. Secondary efficacy endpoints included the weekly subject-reported attack rate, number of attack-free days, the AE-QoL score, and the average attack severity score. Efficacy data collected included the number of angioedema attacks and related details (timing, severity, duration of symptoms, anatomical location, treatment used [if any]), number of attack-free days, Angioedema Quality of Life (AE-QoL) Questionnaire,<sup>14,15</sup> and angioedema activity score (AAS,<sup>16</sup>). An angioedema attack was defined as subject-reported indication of swelling at any location following a report of no swelling on the previous day. Abdominal attacks were defined by abdominal pain with or without nausea or vomiting; laryngeal attacks were defined by difficulty swallowing or breathing, voice change, or lump or tightness in the throat. Peripheral attacks were defined by cutaneous swelling. Prior to inclusion in efficacy analyses, each subject-reported angioedema attack was reviewed by the investigator, and all attacks were reviewed and confirmed or rejected by an expert adjudication panel blinded to treatment arm.

Plasma samples for determination of avoralstat concentrations were collected at baseline (Day 1) and predose (trough) at the Week 4, 8, and 12 visits for all subjects. Subjects who consented to participate in a PK substudy had additional plasma samples drawn through 6 hours following the first dose on Day 1 and for one morning dose at or between the Week 4 and Week 8 visits.

Safety was assessed by monitoring of adverse events (AEs) and through clinical laboratory assessments, vital signs, electrocardiograms

(ECGs), abdominal ultrasonography, and physical examinations. An independent data monitoring committee periodically reviewed safety data.

## 2.5 | Populations for analysis

The intent-to-treat (ITT) and safety populations included all subjects who were randomized and received at least 1 dose of study drug.

## 2.6 | Statistical analysis

The primary efficacy endpoint was the angioedema attack rate based on confirmed attacks. The study was designed to investigate the superiority of avoralstat over placebo. Assuming a normalized placebo attack rate of 1 unit and standard deviations of 0.45 and 0.40 units for avoralstat and placebo attack rates, respectively, a sample size of 32 subjects was anticipated to have 90% power to detect a treatment difference of 0.35 units per time period between avoralstat and placebo, based on a 2-sided test at a significance level of 0.05.

An analysis of covariance (ANCOVA) model, including treatment group as a fixed term and angioedema attack stratum ( $\geq 1$  or  $< 1$  attack per week) as a covariate, was used for the primary analysis, which reported the estimated treatment difference in attack rate (for each avoralstat dose minus placebo) with its associated 95% CI and *P*-value.

Secondary efficacy endpoints included the number of attack-free days, the AE-QoL score, the number of subject-reported attacks, and the average attack severity score. Attack-free days were analyzed in a similar manner as the primary efficacy endpoint. Changes from

baseline in AE-QoL data were summarized by the four AE-QoL domain scores and a total score using the appropriate scoring algorithm. Average attack severity score was summarized.

Avoralstat plasma PK parameters were estimated using noncompartmental analysis (Phoenix WinNonlin, version 6.4 or later).

Safety data were summarized descriptively.

## 3 | RESULTS

### 3.1 | Baseline characteristics

The study was conducted from December 2014 to January 2016. Of the 137 subjects screened, 110 subjects were randomized and dosed (Figure 1). Of the 110 subjects randomized, 103 subjects (93.6%) completed study drug and 7 subjects (6.4%) discontinued study drug prior to Week 12. Reasons for study drug discontinuation included AEs (1 subject due to rash and 1 subject due to angioedema attack in the avoralstat 500 mg group), lack of efficacy (1 subject each in the avoralstat 300 mg group and the placebo group), a positive pregnancy test (1 subject in the placebo group), protocol violation (1 subject in the avoralstat 500 mg group), and study non-compliance (1 subject in the placebo group).

The majority of subjects were female (77.3%) and Caucasian (92.7%), the mean age was 41.2 years, and the mean BMI was 26.8 kg/m<sup>2</sup> (Table 1). A small number of subjects (9.1%) continued with concurrent androgen prophylaxis on study. The mean (SD) weekly qualifying attack rate was 0.93 (0.37). Baseline demographics and disease characteristics were generally similar across the treatment groups.

BMI, body mass index; C1-INH-HAE, hereditary angioedema due to C1 inhibitor deficiency; ITT, intent to treat; SD, standard deviation; TID, 3 times per day.

<sup>a</sup>Qualifying HAE attack rate was derived based on subject-reported historical attacks or attacks during the run-in period when historical attack data were not available.

### 3.2 | Primary efficacy measure

The least squares (LS) mean attack rates per week of confirmed attacks were 0.59, 0.68, and 0.59 for subjects during treatment with avoralstat 500 mg, avoralstat 300 mg, and placebo groups, respectively ( $P \geq .5$ , Table 2).

### 3.3 | Secondary efficacy measures

The LS mean attack rates per week of all subject-reported attacks were 0.62, 0.73, and 0.65 for subjects in the avoralstat 500 mg, avoralstat 300 mg, and placebo groups, respectively ( $P \geq .5$ , Table 2). The LS mean attack rates per week of confirmed attacks requiring treatment were 0.49, 0.58, and 0.50 for subjects in the avoralstat 500 mg, avoralstat 300 mg, and placebo groups, respectively (Table 2). The most commonly used medications to treat attacks were icatibant and plasma-derived C1-INH concentrate.

Both the number and percent of attack-free days were similar between active and placebo treatment groups, with approximately 80% of the total days on study treatment attack-free. Overall, 1 subject in each of the avoralstat groups and no subjects in the placebo group were attack-free during the 84-day treatment period. The LS mean duration of all confirmed attacks was 25.4, 29.4, and 31.4 hours for subjects in the avoralstat 500 mg ( $P = .01$ ), avoralstat 300 mg ( $P = .40$ ), and placebo groups, respectively.

The LS mean reduction from baseline (improvement) in total AE-QoL scores in the avoralstat 500 mg group was significantly

greater than in the placebo group at Week 4 ( $-7.23$  points,  $P = .03$ ) and Week 8 ( $-8.83$  points,  $P = .01$ ), but not at Week 12 ( $-5.31$  points,  $P = .16$ ) (Table 3). Greater reductions were observed for the avoralstat 500 mg group compared with placebo for each of the individual domain scores with significant differences observed at specific time points: Weeks 4 and 8 for functioning, Week 8 for fear/shame, and Week 12 for fatigue/mood. No significant differences were observed between the avoralstat 300 mg group and placebo at any time point.

Angioedema activity score scores were not significantly different comparing either 500 mg or 300 avoralstat groups with placebo.

### 3.4 | Pharmacokinetics

Following multiple oral dose administration, maximal avoralstat concentrations were achieved approximately 1 hour postdose. Plasma concentrations are shown in Figure 2. A large variability in plasma concentrations was observed at both doses, with many time points below the target therapeutic concentration of 4-8 times the EC<sub>50</sub> of avoralstat for plasma kallikrein.

### 3.5 | Safety

Avoralstat was generally safe and well tolerated, with only 2 discontinuations due to unrelated AEs (an angioedema attack, considered serious, and a mild rash; both in the avoralstat 500 mg group), and no life-threatening AEs or treatment-related SAEs were

**TABLE 2** Summary of primary and secondary efficacy endpoints (ITT population)

AAS, angioedema activity score; AE-QoL, angioedema quality of life; CI, confidence interval; ITT, intent to treat; LS, least squares; TID, 3 times per day.  
<sup>a</sup>Avoralstat – placebo.

reported. No deaths were reported. Most AEs were mild or moderate in severity. Grade 3 AEs considered related to study drug were flatulence, diarrhea, and abdominal distension in the avoralstat 300 mg group and flatulence and headache in the placebo group. No Grade 3 AEs considered related to study drug were reported in the 500 mg group. No treatment-emergent Grade 4 AEs were reported.

The most commonly reported AEs (Table 4) in the combined avoralstat groups and placebo, respectively, were diarrhea (32.4%, 33.3%), flatulence (20.3%, 25.0%), and nasopharyngitis (17.6%, 19.4%). The nature and frequency of the AEs were generally similar between the avoralstat treatment groups and the placebo group.

Grade 3 or 4 chemistry abnormalities generally occurred in a similar proportion of subjects in the avoralstat and placebo groups. No subject experienced a Grade 3 or 4 hematology or coagulation laboratory abnormality. No notable changes in vital signs (systolic and diastolic blood pressure and pulse) were reported during the study.

## 4 | DISCUSSION

This study failed to confirm the benefit of avoralstat in reducing angioedema attack rates seen in the OPuS-1 Phase 2 study. With the exception of quality of life, no differences were observed in the prespecified secondary endpoints of the study, although the LS mean attack duration for the avoralstat 500 mg group was significantly less than placebo.

The failure of this Phase 3 study was surprising, given the clear treatment effect demonstrated in the earlier Phase 2 study, OPuS-1. A number of factors associated with the PK of avoralstat may explain the poor outcome observed in this study.

Overall, reported study drug compliance was high with a median compliance rate of approximately 99% across all treatment groups. However, trough PK data indicate a wide spread in the time since last recorded dose of study drug, indicating that adherence to an 8-hourly dosing regimen and taking study drug on an empty stomach, which were required due to the short plasma half-life of the drug and known food effect on

**TABLE 3** Summary of the LS mean change from baseline in the total AE-QoL score (ITT population)

<sup>a</sup>A reduction in total score represents an improvement in QoL.

exposure, respectively, was a challenge for study subjects. Intervals between the 3 daily doses were not evenly spaced, with the largest mean interval of approximately 11 hours. Thus, while reported dosing compliance was 99%, dosing frequency (three times daily) and food effect likely impacted efficacy outcomes by contributing to variability in drug exposure.

Plasma concentrations of avoralstat were widely distributed, with many time points showing drug levels below the target therapeutic range of 4–8 times the EC<sub>50</sub> of avoralstat for plasma kallikrein. This variability in exposure was likely due to a combination of the low oral bioavailability of the drug and its relatively rapid clearance,<sup>17</sup> coupled with variation in dosing interval and food effects.

Although there were no significant reductions in angioedema attack rate with avoralstat compared with placebo, there was some evidence suggesting that treatment with avoralstat 500 mg improved quality of life. The AE-QoL scores in the avoralstat 500-mg group showed a significant reduction (improvement) compared to placebo at Weeks 4 and 8; however, the difference was not significant at Week 12. QoL measures are increasingly being incorporated into HAE treatment trials as clinically meaningful endpoints. While clearly insufficient to prove efficacy in this study, the difference in QoL scores between the avoralstat 500 mg group and placebo treatment groups is intriguing as a potential indirect marker of pharmacodynamic effect.

Overall, treatment with avoralstat 500 or 300 mg 3 times daily for 12 weeks was generally safe and well tolerated with no treatment-related SAEs. Gastrointestinal side effects were most common, but did not lead to treatment discontinuation. Gastrointestinal events common to all groups were most likely due to excipients as the rates of these events were similar in drug-treated and placebo groups.

**FIGURE 2** Avoralstat plasma concentrations. The blue bar represents a target therapeutic concentration in the range of 4–8 times the EC<sub>50</sub> of avoralstat for plasma kallikrein in a plasma-based assay<sup>17</sup>

In summary, this rigorous randomized controlled trial of avoralstat did not demonstrate efficacy in preventing angioedema attacks in C1-INH-HAE patients. However, the study provided evidence of shortened angioedema episodes and improved QoL measures in the avoralstat 500 mg treatment group compared to placebo, and established safety of oral kallikrein inhibition in this study cohort.

In the future, additional compounds of this drug class with improved pharmacokinetic and pharmacodynamic profiles may be of substantial therapeutic benefit in C1-INH-HAE. Ongoing

**TABLE 4** Adverse events occurring in  $\geq 5\%$  of subjects in any treatment group (safety population)

	Avoralstat 500 mg TID (N = 38)	Avoralstat 300 mg TID (N = 36)	Placebo (N = 36)	Avoralstat total (N = 74)

TID, 3 times per day.

Adverse events were coded using Medical Dictionary for Regulatory Activities (MedDRA) version 16.0. Treatment-emergent adverse events included events that started on and after the date of the first dose up to the last dose plus 30 d.

studies are investigating an oral once-daily kallikrein inhibitor with improved bioavailability and a longer half-life.

## ACKNOWLEDGMENTS

We thank all of the patients and study teams for their commitment to this study and Aubri Charboneau and Caren Carver of Sage Scientific Writing, LLC for writing and editorial assistance.

## CONFLICTS OF INTEREST

This study was sponsored by BioCryst Pharmaceuticals, Inc (BioCryst), Durham, NC. Dr. Riedl reports grants from BioCryst during the conduct of the study; grants and personal fees from BioCryst, CSL Behring, Shire, and Pharming; and personal fees from Adverum, Alnylam, Ionis, and Kalvista outside the submitted work. Dr. Aygören-Pürsün reports grants from BioCryst during the conduct of the study;

personal fees and nonfinancial support from BioCryst; grants, personal fees, and nonfinancial support from CSL Behring; grants, personal fees, and nonfinancial support from Shire; and personal fees from Pharming and Adverum outside the submitted work. Dr Baker reports grants from BioCryst during the course of the study. Dr. Farkas reports personal fees from BioCryst during the conduct of the study, and personal fees from CSL Behring, Pharming, and Shire outside the submitted work.
